Abstract: The design of inductors in electromagnetic shaping of molten metals consists of looking for the position and the shape of a set of electric wires such that the induced electromagnetic field makes a given mass of liquid metal acquire a predefined shape. In this paper we formulate an inverse optimization problem where the position and shape of the inductors are defined by a set of design variables. The solution of this problem correspond to the optimal design, i.e., the shape of the liquid metal is as close as possible to the target shape. In a first formulation of the inverse optimization problem we minimize the difference between the target and the equilibrium shapes while in a second approach we minimize the L^2 norm of a fictitious surface pressure that makes the target shape to be in mechanical equilibrium. Geometric constraints that prevent the inductors to penetrate into the liquid metal are considered in both formulations. The optimization problems are solved using FAIPA, a line search interior-point algorithm for nonlinear optimization. Some examples are presented to show the effectiveness of the proposed approaches. .

Optimisation de la forme des inducteurs en magnétoformage

Résumé : La conception d'inducteurs dans le formage électromagnétique de métaux liquides consiste en chercher la position et la forme d'un jeu de fils électriques tel que le champ électromagnétique induit fait qu'une masse donnée de métal liquide acquière une forme prédéterminée. Dans ce papier nous formulons un problème d'optimisation inverse où la position et la forme des inducteurs sont définies par un jeu de variables de conception. La solution de ce problème correspond à la conception optimale, c'est-à-dire, la forme du métal liquide est aussi près que possible d'une forme prédéterminée. Dans une première formulation du problème d'optimisation inverse nous réduisons au minimum la différence entre l'objectif et les formes en équilibre tandis que dans une deuxième approche nous réduisons au minimum la norme L^2 d'une pression superficielle fictive qui fait en sorte que la forme objectif vérifie l'équilibre mécanique. On considère des contraintes géométriques qui empêchent les inducteurs de pénétrer dans le métal liquide dans les deux formulations. Les problèmes d'optimisation sont résolus utilisant FAIPA, un algorithme de points intérieurs pour l'optimisation non-linéaire. Quelques exemples sont présentés pour montrer l'efficacité des approches proposées.

1 Introduction

Electromagnetic Casting (EMC) and Magnetic Suspension Melt Processing (MSMP) are important technologies in the metallurgical industry. They are based on the repulsive forces that an alternating electromagnetic field produces on the surface of some kind of materials. They make use of the electromagnetic field for contactless heating, shaping and control of solidification of hot melts. The EMC has primarily been employed for containerless continuous casting but is mainly used to prepare ingots of aluminum alloy [15]. Another important application, extensively used in aeronautics, astronautics, energy and chemical engineering, is in the manufacturing of components of engines made of superalloy materials (Ni,Ti,...) [14]. Advantages of these techniques are to produce components with high surface quality, high cleanness and low contamination.

The EMC problem studied here concerns the case of a vertical column of liquid metal falling down into an electromagnetic field created by vertical inductors. In Fig. 1

Figure 1: EMC problem.

the horizontal cross-section of the inductors is represented by the domains Θ_p , $1 \leq p \leq 4$, and the cross-section of the liquid metal is represented in the figure by the domain ω . Given the position and shape of the inductors, the magnetic field created by them produces a surface pressure on the vertical column of liquid metal. That surface pressure forces the liquid metal to change its shape until an equilibrium relation on the boundary between the electromagnetic pressures and surface tensions is satisfied. The boundary shape of the liquid metal such that the equilibrium is attained can be found as the solution of a nonlinear free-surface problem, see [24], [25] for details. Our purpose is to design suitable inductors such that the equilibrium shape of the liquid metal be as close as possible to a given target shape.

In a previous work we studied this EMC problem considering the case where the inductors are made of single solid-core wires with a negligible area of the cross-section [13]. Thus, the inductors were represented by points in the horizontal plane. In this paper we consider the more realistic case where each inductor is a set of bundled insulated strands. In this case we represent the inductors by a domain in the plane as depicted by Fig. 1. The electric current density is assumed uniform on the entire cross-section of the inductor. This is a very reasonable approximation for the case where the inductors are made up of multiple individually insulated strands twisted or woven together.

Our goal is to determine the position and shape of the domains Θ_p that represent the cross-section of the inductors in order to have an horizontal cross-section of the molten metal as close as possible to the prescribed shape. For this purpose we consider the two different approaches proposed in [13]. The first one looks for a set of inductors such that minimizes the distance between the computed shape and the given target one. The second approach minimizes the error of the equilibrium equation for the target shape.

In addition, here we introduce a new technique to consider geometric constraints that prevent the inductors to penetrate the liquid metal. These constraints are more suitable than the box constraints considered in [13] making the considered formulations more effective and robust for the solution of the EMC problem.

In this paper we employ a SAND formulation for both approaches and solve the optimization problems employing the *Feasible Arc Interior Point Algorithm*, FAIPA, a line search interior-point algorithm for nonlinear optimization. See [32], [33], [42], [37], [6] for a general discussion of the SAND formulation, [5], [34], [12], [13] for some other issues and applications and [20], [34], [21] for details about FAIPA.

2 The mathematical model of the electromagnetic shaping problem

We assume that the frequency of the imposed current is very high so that the magnetic field does not penetrate into the metal. In other words we neglect the skin effect. Moreover, we assume that a stationary horizontal section is reached so that the 2-dimensional model is valid. The equilibrium of the system is insured by the static balance on the surface of the metal between the surface tension forces and the electromagnetic forces. This problem and other similar ones have been considered by several authors, we refer the reader to the following papers for the physical analysis of the simplifying assumptions that the above model requires: see [9], [18], [19], [22], [40], [24, 10].

We denote by Ω the exterior in the plane of the compact and simply connected domain ω occupied by the cross-section of the metal column; see Fig. 1.

The exterior magnetic field can be found as the solution of the following boundary value problem:

$$\nabla \times \vec{B} = \mu_0 \vec{J} \quad \text{in } \Omega, \quad (1)$$

$$\nabla \cdot \vec{B} = 0 \quad \text{in } \Omega, \quad (2)$$

$$\vec{B} \cdot \nu = 0 \quad \text{on } \Gamma, \quad (3)$$

$$\|\vec{B}\| = O(\|x\|^{-1}) \text{ as } \|x\| \rightarrow \infty \text{ in } \Omega. \quad (4)$$

Here the fields $\vec{J} = (0, 0, J)$ and $\vec{B} = (B_1, B_2, 0)$ represent the mean square values of the current density vector and the total magnetic field, respectively. The constant μ_0 is the vacuum permeability, ν the unit normal vector to the boundary Γ and $\|\cdot\|$ denotes the Euclidean norm. We assume that J has compact support in Ω and satisfies:

$$\int_{\Omega} J dx = 0. \quad (5)$$

On the other hand, the magnetic field produces a surface pressure that acts on the liquid metal, changing the shape until the equilibrium is attained. This equilibrium is characterized by the following equation [24], [25]:

$$\frac{1}{2\mu_0} \|\vec{B}\|^2 + \sigma \mathcal{C} = p_0 \quad \text{on } \Gamma, \quad (6)$$

where \mathcal{C} is the curvature of Γ seen from the metal, σ is the surface tension of the liquid and the constant p_0 is an unknown of the problem. Physically, p_0 represents the difference between the internal and external pressures. Since it is assumed that the molten metal is incompressible, we have the following condition:

$$\int_{\omega} dx = S_0, \quad (7)$$

where S_0 is given.

In the direct problem the electric current density J is given and one needs to find the shape of ω that satisfies (7) and such that the magnetic field \vec{B}_{ω} solution of (1)-(4) satisfies also the equilibrium equation (6) for a real constant p_0 .

Conditions (1)-(5), with the function J compactly supported in Ω , imply that there exists the flux function $\varphi : \Omega \rightarrow \mathbb{R}$ such that $\vec{B} = (\frac{\partial \varphi}{\partial x_2}, -\frac{\partial \varphi}{\partial x_1}, 0)$ and φ is the solution of:

$$\begin{aligned} -\Delta \varphi &= \mu_0 J && \text{in } \Omega, \\ \varphi &= 0 && \text{on } \Gamma, \\ \varphi(x) &= O(1) && \text{as } \|x\| \rightarrow \infty. \end{aligned} \quad (8)$$

Figure 2: Domain perturbation.

The equilibrium equation (6) in terms of the flux φ becomes:

$$\frac{1}{2\mu_0} \|\nabla \varphi\|^2 + \sigma \mathcal{C} = p_0 \quad \text{on } \Gamma. \quad (9)$$

The direct problem, in terms of the flux, consists of looking for a domain ω such that the solution φ_ω of (8) satisfies (9) for a real constant p_0 .

2.1 The variational model of the direct problem

Under suitable assumptions, the equilibrium configurations are given by the local stationary points with respect to the domain of the following total energy:

$$E(\omega) = -\frac{1}{2\mu_0} \int_{\Omega} \|\nabla \varphi_\omega\|^2 dx + \sigma P(\omega), \quad (10)$$

subject to the equality constraint in the measure of ω :

$$\int_{\omega} dx = S_0. \quad (11)$$

In (10), φ_ω is the solution of (8) and $P(\omega)$ is the perimeter of ω , i.e., the length of $\Gamma = \partial\omega$ when $\partial\omega$ is regular enough (for instance of class C^1):

$$P(\omega) = \int_{\Gamma} d\gamma, \quad d\gamma = \text{length measure on } \Gamma. \quad (12)$$

The variational formulation of the direct problem consists of finding the domain ω as a stationary point of the total energy (10), subject to the constraint (11). As φ_ω is solution of (8), to prove that this variational formulation is equivalent to the previous one it remains to show that the equilibrium relation is automatically ensured for all the stationary points.

2.2 First order optimality conditions

In order to derive the first order optimality conditions we consider shape derivatives. Differentiation with respect to the domain is a classical issue, in this work we consider the point of view of F. Murat and J. Simon; see [1], [39], [31].

Let $V \in W^{1,\infty}(\mathbb{R}^2, \mathbb{R}^2)$ the set of the Lipschitz functions ϕ from \mathbb{R}^2 to \mathbb{R}^2 such that ϕ and $\nabla \phi$ are uniformly bounded [1]. Let ω be a bounded domain in \mathbb{R}^2 of class C^2 . We consider a shape deformation given by the mapping $Id + V$, where Id is the identity mapping. Then, the deformed set ω_V is defined by $\omega_V = \{x + V(x) \mid x \in \omega\}$; see Fig. 2.

For every $V \in W^{1,\infty}(\mathbb{R}^2, \mathbb{R}^2)$ the mapping $Id + V$ is a diffeomorphism provided $\|V\|_{W^{1,\infty}(\mathbb{R}^2, \mathbb{R}^2)} < 1$ [1].

Let $\mathcal{O}(\omega)$ be the collection of images of ω considering all possible diffeomorphisms. If F is a scalar function defined in $\mathcal{O}(\omega)$ we said that it is shape differentiable if the function $V \rightarrow F(\omega_V)$ is differentiable at $V = 0$ in the Banach space $W^{1,\infty}(\mathbb{R}^2, \mathbb{R}^2)$.

The derivative of F , defined in $W^{1,\infty}(\mathbb{R}^2, \mathbb{R}^2)$, is called *shape gradient* and is denoted by $F'(\omega)$. It can be shown that the linear application $V \rightarrow F'(\omega)(V)$ is determined by the normal component of V in the boundary of ω , see the works by [1], [7] and [40] for a detailed description of the shape derivative structure.

Let L be the Lagrangian function defined in $\mathcal{O}(\omega) \times \mathbb{R}$ by:

$$L(\omega, p_0) = E(\omega) - p_0(m(\omega) - S_0), \quad (13)$$

Then, the first order optimality condition is the following:

$$L'(\omega, p_0)(V) = 0 \quad \forall V \in W^{1,\infty}(\mathbb{R}^2, \mathbb{R}^2). \quad (14)$$

This kind of optimality conditions often appear in hydrodynamic problems and other fluid problems; let us refer for instance to the work by [10] where a large class of liquid metal equilibria is considered.

Theorem Let Ω be the complement of a compact set ω in \mathbb{R}^2 with nonempty interior. Assume that $\Gamma = \partial\omega = \partial\Omega$ is of class C^2 . Let V be in $W^{1,\infty}(\mathbb{R}^2, \mathbb{R}^2)$ with compact support and $\|V\|_{W^{1,\infty}(\mathbb{R}^2, \mathbb{R}^2)} < 1$. Let F be a square integrable function from Ω into \mathbb{R} with compact support in Ω .

Then, there exists a unique solution φ_{ω_V} in $C^1(\overline{\Omega_V})$ (see [2] and [19]) of:

$$\begin{aligned} -\Delta\varphi_{\omega_V} &= \mu_0 J && \text{in } \Omega_V, \\ \varphi_{\omega_V} &= 0 && \text{on } \partial\Omega_V, \\ \varphi_{\omega_V}(x) &= O(1) && \text{as } \|x\| \rightarrow \infty. \end{aligned} \quad (15)$$

and the shape derivative of the lagrangian L is given by:

$$L'(\omega, p_0)(V) = \int_{\Gamma} \left(\frac{1}{2\mu_0} \|\nabla\varphi_{\omega}\|^2 + \sigma\mathcal{C} - p_0 \right) (V \cdot \nu) d\gamma, \quad (16)$$

where ν is the unit normal to Γ oriented toward Ω , \mathcal{C} is the curvature of Γ (seen from the metal) and φ_{ω} the solution of (8).

Proof See [19], [24], [40], [1].

This problem is very similar to some ones considered by several authors. We refer the readers to the following papers and references therein for the physical analysis of the simplifying assumptions that the above model requires: see [9], [16], [18], [19], [4], [22], [38], [40], [23], [24],[25], [3], [28], [30], [35], [36].

3 The inverse problem

The goal of the inverse problem is to find a distribution of current around the liquid metal column so that it attains a given shape.

Given the target shape ω^* , we want to compute J as the solution of the following optimization problem:

$$\min_J d(\omega, \omega^*), \quad (17)$$

where the function d is a distance between ω and ω^* . The domain ω belongs to the set of admissible domains, i.e., $\omega \in \mathcal{O}$, and is in equilibrium under the action of the

electric current density J in the variational sense. In other words, ω satisfies the area constraint (11) and the flux φ_ω solution of (8) satisfies the equilibrium equation (18) for a real constant p_0 :

$$\int_{\Gamma} \left(\frac{1}{2\mu_0} \|\nabla \varphi_\omega\|^2 + \sigma \mathcal{C} - p_0 \right) (V \cdot \nu) d\gamma = 0 \quad \forall V \text{ in } C^1(\mathbb{R}^2, \mathbb{R}^2). \quad (18)$$

From a practical point of view, the magnetic field has to be created by a simple configuration of inductors. For that purpose, we consider a distribution of the electric current density J of the form:

$$J = I \sum_{p=1}^m \alpha_p \chi_{\Theta_p}, \quad (19)$$

where I is a given intensity of current, Θ_p , with $1 \leq p \leq m$, are subsets of \mathbb{R}^2 , χ_{Θ_p} are their characteristic functions, and α_p are dimensionless coefficients. Then, the inverse problem consists of determining the sets Θ_p .

Note that the expression (19) assumes that the electric current density is uniform on each region Θ_p . Inductors made of bundled insulated strands allow the use of (19) as a good approximation, see [8] and references therein. They are also suitable to make inductors of specific geometries.

For an electric current density given by (19), (5) is satisfied imposing:

$$\sum_{p=1}^m \alpha_p \int_{\Theta_p} dx = 0. \quad (20)$$

Remark 1. In certain cases it is possible to find a current density distribution such that the target shape ω^* is in equilibrium. This topic was already studied and there are a few papers about the existence of such solutions. See [19], [17], [26].

In the two-dimensional case, ω^* is assumed simply connected and its boundary is only one Jordan curve Γ . [19], show that a solution of (1), (2), (3), (4), and (6), with J compactly supported in Ω can be found for each p_0 satisfying:

$$p_0 \geq \sigma \max_{x \in \Gamma} \mathcal{C}(x), \quad (21)$$

That is, assuming J compactly supported in Ω , and choosing p_0 satisfying (21), then there exists \bar{B} satisfying (1), (2), (3), (4), and (6) if and only if:

- (i) Γ is an analytic curve.
- (ii) If p_0 is chosen satisfying the equality in (21), the global maximum of the curvature must be attained in an even number of points.

Moreover, the magnetic field is well determined in a neighborhood of ω (local uniqueness).

Equation (5) is also obtained if p_0 is chosen satisfying the equality in (21). A current density distribution concentrated on a curve in Ω can always be found. However, a solution given by the addition of a finite number of characteristic functions like (19) may be not possible. See [19].

3.1 Two approaches for the inverse problem

We propose two different approaches for finding an approximate solution of problem (17). The first one considers a domain deformation of ω^* defined by the mapping:

$$T_Z(x) = x + Z(x), \quad \forall x \in \mathbb{R}^2, \quad (22)$$

where Z is a regular vector field with compact support in \mathbb{R}^2 . Then, defining:

$$\begin{aligned} \omega_Z &= T_Z(\omega^*), \\ \Gamma_Z &= T_Z(\Gamma^*). \end{aligned}$$

The first inverse formulation is:

$$\begin{aligned} &\min_{J, Z} \|Z\|_{L^2(\Gamma^*)}^2, \\ &\text{subject to:} \\ &\omega_Z \text{ is in equilibrium under } J. \end{aligned} \quad (23)$$

A second formulation of the inverse problem can be considered introducing a slack variable function $p(x) : \Gamma \rightarrow \mathbb{R}$ in order to make the equilibrium equation satisfied for the target shape:

$$\begin{aligned} \int_{\Gamma^*} \left(\frac{1}{2\mu_0} \|\nabla \phi_\omega\|^2 + \sigma \mathcal{C} - p_0 + p \right) (V \cdot \nu) d\gamma = 0 \\ \forall V \in C^1(\mathbb{R}^2, \mathbb{R}^2). \end{aligned} \quad (24)$$

The function p can be understood as an additional pressure acting on the interface. Given J and ω^* , p is the surface pressure that equilibrates the action of the magnetic pressure and the surface tension. The second formulation for the inverse problem is an indirect approach that try to minimize the $L^2(\Gamma^*)$ norm of the function p :

$$\begin{aligned} &\min_{J, p} \|p\|_{L^2(\Gamma^*)}^2, \\ &\text{subject to:} \\ &\omega^* \text{ is in equilibrium under } J \text{ and } p. \end{aligned} \quad (25)$$

Remark 2. In this last formulation only shape variables concerning the inductors are considered. This fact makes (25) much easier to solve than (23). If the function p vanishes at the solution of (25), the resulting electric current density J will also be a solution of the first formulation with the equilibrium domain matching exactly the target shape. In the general case, p will not vanish at the solution and, in this case, the target shape ω^* will not be in equilibrium under J only. Then, a second stage of analysis will be necessary to find the equilibrium domain under the obtained current density distribution. However, as the norm of p was minimized, the resultant equilibrium domain is expected to be a good approximation of the target one. Furthermore, since (25) can be solved with a minor computational effort, its solution J can be employed as an initial guess for the formulation (23).

4 Numerical Method

4.1 The exterior Dirichlet problem

To solve (8) in the exterior domain Ω we consider a particular solution φ_1 of the differential equation given by:

$$\varphi_1(x) = -\frac{\mu_0}{2\pi} \int_{\mathbb{R}^2} \ln \|x-y\| J(y) dy. \quad (26)$$

This function is a solution of the problem:

$$-\Delta \varphi_1(x) = \mu_0 J \quad \text{in } \mathbb{R}^2, \quad (27)$$

$$\varphi_1(x) = O(1) \quad \text{as } \|x\| \rightarrow \infty. \quad (28)$$

Note that for the current density distribution defined by (19), the expression of φ_1 is

$$\varphi_1(x) = -\frac{\mu_0 I}{2\pi} \sum_{p=1}^m \alpha_p \int_{\Theta_p} \ln \|x-y\| dy. \quad (29)$$

The function φ_1 can be calculated as a sum of line integrals on the boundaries Γ_p of domains Θ_p . Consider the function $w : \mathbb{R}^2 \times \mathbb{R}^2 \rightarrow \mathbb{R}^2$ defined as:

$$w(x, y) = (1/4)(1 - 2 \ln \|x-y\|)(x-y). \quad (30)$$

The divergence of w is $\nabla_y \cdot w = \ln \|x-y\|$. Then, (29) becomes:

$$\varphi_1(x) = -\frac{\mu_0 I}{2\pi} \sum_{p=1}^m \alpha_p \int_{\Gamma_p} w(x, y) \cdot \nu d\gamma. \quad (31)$$

The function φ can be computed as:

$$\varphi(x) = \xi(x) + \varphi_1(x), \quad (32)$$

where the function ξ is the solution of the following exterior problem:

$$\begin{aligned} -\Delta \xi(x) &= 0 && \text{in } \Omega, \\ \xi(x) &= -\varphi_1(x) && \text{on } \Gamma, \\ \|\xi(x)\| &= O(1) && \text{as } \|x\| \rightarrow \infty. \end{aligned} \quad (33)$$

Following [2], an integral single layer representation of the solution of (33) is given by:

$$\xi(x) = -\frac{1}{2\pi} \int_{\Gamma} q(y) \ln \|x-y\| d\gamma + c, \quad (34)$$

where the constant c is the value at the infinity of ξ and the function $q(y) \in H^{-1/2}(\Gamma)$ satisfies:

$$\int_{\Gamma} q(y) d\gamma = 0. \quad (35)$$

It remains to impose the boundary conditions on Γ . Here, this is done with a weak formulation. Let $a_{\Gamma}(q, g)$ be the following elliptic bilinear form:

$$a_{\Gamma}(q, g) = -\frac{1}{2\pi} \int_{\Gamma} g(x) \int_{\Gamma} q(y) \ln \|x-y\| d\gamma d\gamma +$$

$$+c \int_{\Gamma} g(x) d\gamma \quad (36)$$

defined on $H^{-1/2}(\Gamma) \times H^{-1/2}(\Gamma)$. We look for a function $q(y) \in H^{-1/2}(\Gamma)$ that satisfies (35) and:

$$a_{\Gamma}(q, g) = - \int_{\Gamma} \varphi_1(x) g(x) d\gamma \quad \forall g \in H^{-1/2}(\Gamma). \quad (37)$$

Finally, the norm $\|\nabla \varphi\|$ in (18) can be computed as:

$$\|\nabla \varphi\| = \left| \frac{\partial \varphi}{\partial \nu} \right| = \left| \frac{\partial \varphi_1}{\partial \nu} + \frac{\partial \xi}{\partial \nu} \right|, \quad (38)$$

where the first equality comes from the fact that φ is constant on Γ , and the second one from (32). The normal derivative of φ_1 is obtained from (31):

$$\frac{\partial \varphi_1}{\partial \nu_x}(x) = -\frac{\mu_0 I}{2\pi} \sum_{p=1}^m \alpha_p \int_{\Gamma_p} \frac{\partial}{\partial \nu_x} (w(x, y) \cdot \nu) d\gamma. \quad (39)$$

The following expression can be used for ξ :

$$\frac{\partial \xi}{\partial \nu_x}(x) = -\frac{1}{2\pi} \int_{\Gamma} q(y) \frac{\partial}{\partial \nu_x} \ln \|x - y\| d\gamma + \frac{1}{2} q(x) \quad \forall x \in \Gamma, \quad (40)$$

where the integral of (40) is understood in the Cauchy principal value sense.

4.2 The SAND formulation of the inverse problems

A SAND formulation of the inverse problems (23) and (25) is employed here. In other words, the state variables p_0 , c and q are incorporated as unknowns of the optimization problem and the state and equilibrium equations are incorporated as equality constraints. The optimization problem of the formulation (23) becomes:

$$\min_{J, Z, p_0, c, q} \|Z\|_{L^2(\Gamma^*)}^2, \quad (41)$$

subject to the area constraint:

$$\int_{\omega_Z} dx = S_0, \quad (42)$$

the state equations:

$$a_{\Gamma_Z}(q, g) = - \int_{\Gamma_Z} \varphi_1(x) g(x) d\gamma \quad \forall g \in H^{-1/2}(\Gamma_Z), \quad (43)$$

$$\int_{\Gamma_Z} q(y) d\gamma = 0, \quad (44)$$

and the equilibrium equation:

$$\int_{\Gamma_Z} \left(\frac{1}{2\mu_0} \|\nabla \varphi\|^2 + \sigma \mathcal{E} - p_0 \right) (V \cdot \nu) d\gamma = 0 \quad \forall V \text{ in } C^1(\mathbb{R}^2, \mathbb{R}^2), \quad (45)$$

where φ_1 , φ , and ξ are given by (26), (32) and (34).

The optimization problem of the formulation (25) becomes:

$$\min_{J,p,p_0,c,q} \|p\|_{L^2(\Gamma^*)}^2, \quad (46)$$

subject to the state equations:

$$a_{\Gamma^*}(q,g) = - \int_{\Gamma^*} \varphi_1(x) g(x) d\gamma \quad \forall g \in H^{-1/2}(\Gamma^*), \quad (47)$$

$$\int_{\Gamma^*} q(y) d\gamma = 0, \quad (48)$$

and the equilibrium equation:

$$\int_{\Gamma^*} \left(\frac{1}{2\mu_0} \|\nabla \varphi\|^2 + \sigma \mathcal{C} - p_0 + p \right) (V \cdot \nu) d\gamma = 0 \quad \forall V \text{ in } C^1(\mathbb{R}^2, \mathbb{R}^2). \quad (49)$$

4.3 The numerical model

4.3.1 Discretization of the domain

We consider an approximation of the domain ω^* defined by the piecewise linear closed boundary Γ^h , i.e., Γ^h is the union of the n linear finite elements ℓ_j in \mathbb{R}^2 , $j \in \{1, \dots, n\}$. The nodes of the boundary Γ^h are denoted by x_i .

A direction $\hat{Z}^i \in \mathbb{R}^2$ is associated to each vertex x_i of Γ^h . We construct a continuous piecewise linear vector field Z^i from Γ^h in \mathbb{R}^2 such that $Z^i(x_k) = \delta_{ik} \hat{Z}^i$. The support of Z^i is equal to the union of the finite elements for which x_i is a node. The vector field Z of (22) is computed as:

$$Z(x) = \sum_{i=1}^n u_i Z^i(x), \quad (50)$$

and the updated boundary $\Gamma_{\vec{u}}$ is then given by:

$$\Gamma_{\vec{u}} = \left\{ X \mid X = x + Z(x); u_i \in \mathbb{R}, x \in \Gamma^h \right\}, \quad (51)$$

where $\vec{u}^T = (u_1, \dots, u_n) \in \mathbb{R}^n$ is the vector of unknowns which determine the evolution of the boundary. This representation has the advantage of defining only one degree of freedom for each node. We denote by $\omega_{\vec{u}}$ the interior domain related to $\Gamma_{\vec{u}}$ in order to show the dependence with respect to the vector \vec{u} .

4.3.2 Inductors

Each inductor has a geometry corresponding to one of the parametric shapes given by Fig. 3. The contribution of each inductor to the function φ_1 is calculated using (31). The boundary Γ_p of each inductor is divided in small linear elements to perform the integration. The entire set of shape parameters corresponding to the inductors is denoted by \vec{u}_p .

Figure 3: Geometry of the inductors and shape parameters. **1.** four-parameter inductor of rectangular shape; **2.** six-parameter inductor of parabolic vertical sides; **3.** six-parameter inductor of parabolic horizontal sides.

4.3.3 Exterior boundary value problem

For numerical calculations we consider a piecewise constant approximation $q_h(x)$ of $q(x)$:

$$q_h(x) = \sum_{j=1}^n q_j e_j(x), \quad (52)$$

where $e_j(x) = 1$ if $x \in \ell_j$ and zero elsewhere.

Replacing the function g in (43) by e_i , with $i \in \{1, \dots, n\}$, the weak formulation of the boundary value problem, given by equations (43) and (44), becomes:

$$\vec{A}(\vec{u})\vec{q} = \vec{b}(\vec{u}_p, \vec{u}), \quad (53)$$

where the vector $\vec{q}^T = (q_1, \dots, q_n, c)$ is in \mathbb{R}^{n+1} , \vec{u} is the vector of shape variables and \vec{u}_p is the vector that contains the shape parameters of the inductors. The coefficients a_{ij} of the symmetric matrix $\vec{A}(\vec{u})$ are:

$$a_{ij}(\vec{u}) = -\frac{1}{2\pi} \int_{\ell_i} \int_{\ell_j} \ln \|x - y\| d\gamma d\gamma \quad i, j \in \{1, \dots, n\}, \quad (54)$$

$$a_{ij}(\vec{u}) = \int_{\ell_j} d\gamma \quad i = n+1, \text{ and } j \in \{1, \dots, n\}, \quad (55)$$

and the components b_i of the vector \vec{b} are:

$$b_i(\vec{u}_p, \vec{u}) = -\int_{\ell_i} \varphi_1(x) d\gamma \quad i \in \{1, \dots, n\}, \quad (56)$$

$$b_i(\vec{u}_p, \vec{u}) = 0 \quad i = n+1, \quad (57)$$

Remark 3. For given vectors \vec{u} and \vec{u}_p , the linear system (53) is symmetric and non-sparse. Numerical approximations of the element integrals of previous and later equations are computed by Gauss quadrature.

Remark 4. If q is the solution of the system (35), (37) and the piecewise constant approximation q_h given by the solution of (53), then we have the following error bounds (see [41]):

$$\|q - q_h\|_{H^{-1/2}(\Gamma)} \leq C_1 h \|q\|_{H^1(\Gamma)}, \quad (58)$$

and if ξ_h is the approximation of (34) then

$$\left\| \frac{\partial \xi}{\partial \nu} - \frac{\partial \xi_h}{\partial \nu} \right\|_{H^{-1/2}(\Gamma)} \leq C_2 h \|q\|_{H^1(\Gamma)}. \quad (59)$$

Remark 5. The approximation of the normal derivative $\frac{\partial \xi}{\partial \nu}$ at $x_l \in \ell_l$ is given by:

$$\frac{\partial \xi_h}{\partial \nu}(x_l) = -\frac{1}{2\pi} \sum_{\substack{i=1 \\ i \neq l}}^n q_i \sum_{m=1}^K p_m \frac{\partial \ln \|x_l - x_i(s_m)\|}{\partial \nu} + \frac{1}{2} q_l, \quad (60)$$

where $x_i(s_m)$ are the integration points and p_m the weights of the Gauss quadrature formula. Thus, the computation of $\frac{\partial \xi_h}{\partial \nu}(x_l)$ needs $O(n)$ floating point operations.

4.3.4 Equilibrium equation

Consider a direction $\hat{V}^i \in \mathbb{R}^2$ associated to each vertex x_i of Γ^h and the continuous piecewise linear vector field V^i from Γ^h in \mathbb{R}^2 such that $V^i(x_k) = \delta_{ik} \hat{V}^i$. If we project the equation (45) in the finite dimensional space generated by V^i , $i \in \{1, \dots, n\}$, the discrete version of the equilibrium is the following:

$$DE_i(\bar{u}_p, \bar{u}, \bar{q}, p_0) = \int_{\Gamma_{\bar{u}}} \left(\frac{1}{2\mu_0} \|\nabla \varphi\|^2 - p_0 \right) (V^i \cdot \nu) d\gamma + \sigma \mathcal{C}^i \cdot \hat{V}^i, \quad (61)$$

where $i \in \{1, \dots, n\}$ and \mathcal{C}^i is an approximation of the mean curvature at x_i , given by:

$$\mathcal{C}^i = \left(\frac{(x_i - x_{i-1})}{\|x_i - x_{i-1}\|} - \frac{(x_{i+1} - x_i)}{\|x_{i+1} - x_i\|} \right). \quad (62)$$

The gradient $\nabla \varphi$ is computed using (38), (39) and (40).

In the case of equation (49), we consider a piecewise linear function p_h defined as:

$$p_h(x) = \sum_{i=1}^n p_i f_i, \quad (63)$$

where the function f_i satisfies $f_i(x_k) = \delta_{ik}$. Then, defining $\vec{p}^T = (p_1, \dots, p_n)$, the equilibrium equation is defined as:

$$DF_i(\bar{u}_p, \vec{p}, \bar{q}, p_0) = \frac{1}{2\mu_0} \int_{\Gamma^*} (\|\nabla \varphi\|^2 - p_0 + p_h) (V^i \cdot \nu) d\gamma + \sigma \mathcal{C}^i \cdot \hat{V}^i. \quad (64)$$

Figure 4: Geometric constraints.

4.3.5 Geometric constraints

Some geometric constraints are needed to prevent the penetration of the inductors into the liquid metal. That is done here considering the following inequalities:

$$\psi(x_j) \leq \psi_0, \quad \text{for all } x_j \in \vec{X}, \quad (65)$$

where \vec{X} is a chosen set of points belonging to the boundary of the inductors. The real valued function ψ is zero in the interior of the liquid metal and negative in the exterior. Then, choosing a negative value for the parameter ψ_0 , (65) enforces the points x_j to be in the exterior of the liquid metal as illustrated by Fig. 4.

The function ψ is defined as the solution of:

$$\begin{aligned} \Delta\psi(x) &= 0 && \text{in } \Omega^*, \\ \psi(x) &= 0 && \text{on } \Gamma^*, \\ \int_{\Gamma^*} \nabla\psi(x) \cdot \nu d\gamma &= -1. \end{aligned} \quad (66)$$

Like function ξ of Section 4.1, ψ can be calculated as:

$$\psi(x) = -\frac{1}{2\pi} \int_{\Gamma} q(y) \ln \|x - y\| d\gamma + c, \quad (67)$$

where q must satisfy:

$$\int_{\Gamma} q(y) d\gamma = -1. \quad (68)$$

In a similar way as in Section 4.3.3, an approximated solution of q and c can be obtained solving a linear system similar to (53). The numerical approximation of the function ψ is obtained employing (67).

The value ψ_0 can be defined choosing a point in the exterior of the liquid metal and calculating the value of the function ψ at this point. See Figs. 5 and 6 that show the function ψ for two different target shapes.

Defining $\vec{h}_j(\vec{u}_p) = \psi(x_j(\vec{u}_p)) - \psi_0$, all the geometric constraints are expressed as:

$$\vec{h}(\vec{u}_p) \leq 0. \quad (69)$$

Figure 5: Function ψ for a rectangular like target shape.Figure 6: Function ψ for a “T” like target shape.

4.4 Discretized inverse problems

Let the area function be $S(\vec{u}) = \int_{\omega_i} dx$, and $DE(\vec{u}_p, \vec{u}, \vec{q}, p_0)$ the vector function such that $(DE)_i = DE_i(\vec{u}_p, \vec{u}, \vec{q}, p_0)$. The discretized version of the first inverse problem is the following:

$$\min_{\vec{u}_p, \vec{u}, \vec{q}, p_0} \|Z\|_{L^2(\Gamma^*)}^2, \quad (70)$$

subject to the nonlinear equality constraints:

$$\begin{pmatrix} \vec{A}(\vec{u})\vec{q} - \vec{b}(\vec{u}_p, \vec{u}) \\ S(\vec{u}) - S_0 \\ DE(\vec{u}_p, \vec{u}, \vec{q}, p_0) \end{pmatrix} = 0, \quad (71)$$

and the nonlinear inequalities:

$$\vec{h}(\vec{u}_p) \leq 0. \quad (72)$$

The discretized version of the second inverse problem is:

$$\min_{\vec{u}_p, \vec{q}, c, p_0} \|p\|_{L^2(\Gamma^*)}^2, \quad (73)$$

with the equality constraints:

$$\begin{pmatrix} \vec{A}\vec{q} - \vec{b}(\vec{u}_p) \\ DF(\vec{u}_p, \vec{p}, \vec{q}, p_0) \end{pmatrix} = 0, \quad (74)$$

and the nonlinear inequalities:

$$\vec{h}(\vec{u}_p) \leq 0. \quad (75)$$

In this case, since the integrals are defined on the fixed domain Γ^* the vector \vec{u} of shape variables is not present in the formulation.

5 Numerical examples

We consider several examples to illustrate the behavior of the proposed formulations of the inverse problem. The goal is to identify the position and shape of the inductors given by the shape variables \vec{u}_p . The shape and the surface S_0 of the target shape, the surface tension σ , the intensity I and the dimensionless coefficients α_p are given. For each example all the parameters, including the parameters ψ_0 of the geometric constraints, are the same for both formulations. The initial values of the state variables \vec{q} and p_0 , the shape variable \vec{u} of the first formulation and the pressure \vec{p} of the second one are set equal to zero for all the examples.

For the solution of the optimization problems, the line search interior-point algorithm for nonlinear constrained optimization problems FAIPA was employed. For a given feasible point with respect to the inequality constraints, FAIPA defines a feasible and descent arc solving three linear systems of equations with the same coefficient matrix. Then, it performs a line search along this arc to define the next iterate. FAIPA makes subsequent iterations until a certain convergence criterion is satisfied. For more details about FAIPA see [20], [34], [21]. The number of iterations of FAIPA was limited to 400 in all the examples.

For each example we plot the initial position and shape of the inductors, the target shape of the liquid metal and shape of the inductors obtained by the optimization algorithm.

5.1 Example 1

The target shape of this example is the solution of the direct free-surface problem considering four concentrated intensities of value $I = 0.1$, with the sign given by Fig. 7; see [Example 1a] [13].

For the inverse problem we consider four inductors of type 1 of Fig. 3, and a target shape of area S_0 equal to π . The intensity I is equal to 0.1 and the surface tension σ is equal to 1.0×10^{-4} . The dimensionless coefficients α_p have absolute value equal to 4.0 with the sign given by Fig. 8; two configurations for the initial positions of the inductors, named Ex 1a and Ex 1b, are considered as depicted by the figure.

The configuration of inductors obtained was the same for both initial configurations and both formulations. The equilibrium shape obtained is almost the same that the target one and none of the geometric constraints is active at the solution. Fig. 9 shows the inductors obtained and some level curves of the flux function ϕ at the solution.

Employing the first formulation and starting from the initial configuration of Fig. 8.a, the optimization algorithm found the solution in just 7 iterations, but otherwise the number of iterations was large when starting from the configuration of Fig. 8.b. When the second formulation was used, the algorithm solves the problem at very reasonable cost, and with a very good accuracy as Table 1 shows.

5.2 Example 2

In this example the target shape is the rounded square depicted by Fig. 10. For the inverse problem we consider four inductors of type 1 of Fig. 3, and a target shape of area S_0 equal to 3.86. The intensity I is equal to 0.1 and the surface tension σ is equal to 1.0×10^{-4} . The dimensionless coefficients α_p have absolute value equal to 4.0 with the sign given by Fig. 10. Four different values of the parameter ψ_0 of the geometric constraints are considered, these values generate four different problems that we have

named Ex2a to Ex2d, as shown by the Fig. 10. The example Ex2a corresponds to the constraint given by the closest curve to the target shape while the example Ex2d corresponds to the the farthest one.

For the first formulation, the same configuration of the inductors was obtained for all cases as shown by Fig. 11.a; the equilibrium shape and some level curves of the flux function φ at the solution is depicted by Fig. 11.b. The geometric constraints were not active in all the examples using this formulation. Employing the second formulation, the final configuration of inductors depends on the value of the parameter ψ_0 . For the larger value, Fig. 12.a shows the inductors obtained and Fig. 12.b depicts the equilibrium shape and some level curves of the flux function φ at the solution. Figure 13 shows the same for the smaller value of ψ_0 . Different from the first formulation, the second one has the solution having the inductors as close as the liquid metal as possible. In the four cases the geometric constraint is active. Although the location of the inductors is quite different using one or the other formulation, the optimum value of the objective function of the first formulation is almost the same for all the results obtained.

Figure 15: Solution of example Ex3a, first formulation, **a** solution and geometric constraint, **b** equilibrium shape and level curves of the flux function φ .

5.3 Example 3

The target shape of this example is the bar depicted by Fig. 14. For the inverse problem we consider eight inductors of type 1 of Fig. 3, and a target shape of area S_0 equal to 7.86. The intensity I is equal to 0.1 and the surface tension σ is equal to 1.0×10^{-4} . The dimensionless coefficients α_p have absolute value equal to 4.0 with the sign given by Fig. 14. The solutions for two different values of the parameter ψ_0 , named Ex3a and Ex3b, are compared.

In this example, the main difference employing one or the other formulation is the size of the inductors located on left and right side. This size depends strongly on the value of the parameter ψ_0 when using the first formulation but weakly employing the second one. For the larger value and for the first formulation, Fig. 15.a shows the inductors obtained and Fig. 15.b depicts the equilibrium shape and some level curves of the flux function φ at the solution. Figures 16.a and 16.b show the same for the second formulation.

5.4 Example 4

This example has the only difference with respect to the previous one in the sign of the coefficients α_p as depicted by Fig. 17. For the larger value of the parameter ψ_0 and for the first formulation, Fig. 18.a shows the inductors obtained and Fig. 18.b depicts the equilibrium shape and some level curves of the flux function φ at the solution. Figures 19.a and 19.b show the same for the second formulation.

Figure 16: Solution of example Ex3a, second formulation, **a** solution and geometric constraint, **b** equilibrium shape and level curves of the flux function φ .

Figure 17: Example 4, initial configuration and geometric constraints of examples Ex4a and Ex4b. Dash-dot line: target shape, solid line: curves $\psi(x) = \psi_0$ for four different values of ψ_0 , plus: inductor of positive current, circle: inductor of negative current.

Figure 20: Example 5, initial configuration. Dash-dot line: target shape, solid line: curves $\psi(x) = \psi_0$ for four different values of ψ_0 , plus: inductor of positive current, circle: inductor of negative current.

Figure 21: Solution of the example Ex5, first formulation, **a** solution and geometric constraint, **b** equilibrium shape and level curves of the flux function ϕ .

Figure 22: Solution of the example Ex5, second formulation, **a** solution and geometric constraint, **b** equilibrium shape and level curves of the flux function ϕ .

5.5 Example 5

The target shape of this example is the bar depicted by Fig. 20. For the inverse problem we consider eight inductors. The inductors on the top and bottom side are of type 3 of Fig. 3 while the inductors on the left and right side are of type 1. The target shape has S_0 equal to 4.99, the intensity I is equal to 0.1 and the surface tension σ is equal to 1.0×10^{-4} . The dimensionless coefficients α_p have absolute value equal to 4.0 with the sign given by Fig. 20.

The optimization algorithm was unable to solve this example employing the first formulation. A large distortion of the mesh related to the liquid metal was observed in the last iterations. For the second formulation, Fig. 22.a shows the inductors obtained and Fig. 22.b depicts the equilibrium shape and some level curves of the flux function ϕ at the solution.

5.6 Example 6

This example has the only difference with respect to the previous one in the sign of the coefficients α_p as depicted by Fig. 23. For the larger value of the parameter ψ_0 and

Figure 23: Example 6, initial configuration. Dash-dot line: target shape, solid line: curves $\psi(x) = \psi_0$ for four different values of ψ_0 , plus: inductor of positive current, circle: inductor of negative current.

Figure 24: Solution of the example Ex6, first formulation, **a** solution and geometric constraint, **b** equilibrium shape and level curves of the flux function φ .

Figure 25: Solution of the example Ex6, second formulation, **a** solution and geometric constraint, **b** equilibrium shape and level curves of the flux function φ .

for the first formulation, Fig. 24.a shows the inductors obtained and Fig. 24.b depicts the equilibrium shape and some level curves of the flux function φ at the solution. Figures 25.a and 25.b show the same for the second formulation. As the figures show, the solutions of the considered formulations are very different in this case. That shows that the results of the second formulation have to be used with caution, its solution can be far different from the best design of the first formulation.

5.7 Summary of results

Table 1 resumes the information about the considered examples. For each one we give the number of nodes used for the finite element approximation of the boundary Γ^* of the target shape and the number of inductors. For each formulation the number of iterations performed by the optimization algorithm is indicated as well as the final value of the objective function. For the second formulation it is also indicated the final value of the objective function of the first formulation, it was calculated solving the free-surface problem considering the inductors obtained by the optimization algorithm. As one could expect, the first formulation shows smaller values of its objective function in all the examples with the only exception of the examples Ex1a and Ex1b where the shape of the inductors at the solution is almost the same.

Table 1: Summary of results.

Example	Nodes	Inductors	First formulation		Second formulation ^a		
			Iterations	Obj. F1 ^b	Iterations	Obj. F1 ^b	Obj. F2 ^b

(a) F1: first formulation, F2: second formulation.

6 Conclusions

This paper deals with the shape design of inductors concerning the electromagnetic casting of molten metals. Two different approaches based on nonlinear optimization has been proposed in order to find the position and shape of suitable inductors. The first one minimizes the difference between the geometries of the best possible equilibrium domain and the target shape; the second minimizes a slack variable function related to the equilibrium equation on the target boundary. We have also shown how to consider geometric constraints that prevent the inductors to penetrate into the liquid metal. The finite dimensional optimization problems obtained after discretization were solved employing the line search interior-point algorithm FAIPA.

Some presented examples show that both formulations are effective to design suitable inductors. However, the formulations are not equivalent judging by the results obtained for the examples Ex2a-Ex2d and Ex6. The first formulation has shown to be more convenient due to the fact that it found better solutions for almost all the examples. The second formulation could find solutions with similar optimal value of the objective function in most of the cases, but the last presented example has shown that its solution can be, qualitatively, far different from the best design of the first formulation. However, it is less time consuming because of the lack of the shape variables related to the liquid metal. Thus, as most of the results are similar, this formulation appear to be interesting for finding an initial guess for the first formulation.
